\*Historically, the area of defined risk has been a distance of <3 feet around the patient and is based on epidemiologic and simulated studies of

selected infections 103, 104. Using this distance for donning masks has been effective in preventing transmission of infectious agents via the droplet route. However, experimental studies with smallpox 107, 108 and investigations during the global SARS outbreaks of 2003 101 suggest that droplets from patients with these two infections could reach persons located 6 feet or more from their source.
